NX-OS On-Box Automation

Guest Shell Config Drift Auditor

Project Documentation & Technical Reference

Device	Cisco Nexus N9K-C93180YC-EX
Platform	NX-OS with Guest Shell (Python 3.6)
Project Type	On-Box Network Automation
Category	Config Compliance / Drift Detection
Date	April 2026

Prepared by: Praneeth | Data & Network Engineer

Tools: NX-OS Guest Shell • Python 3.6 • vsh • cron

1. Project Overview

This project implements an **on-box configuration drift detection system** running entirely inside the Cisco Nexus 93180YC-EX switch. Using NX-OS Guest Shell and Python, the auditor automatically compares the device's live running configuration against a known-good baseline and logs any deviations with precise timestamps — with zero dependency on any external laptop, server, or management platform.

Why This Matters

Configuration drift is one of the leading causes of network outages and security incidents in enterprise environments. When engineers make undocumented changes — even minor ones — the resulting inconsistency between intended and actual configuration can cause routing failures, policy violations, or compliance gaps. This tool provides continuous, automated visibility into exactly what changed and when.

How It Works — Flow

Step	Component	Action
1	NX-OS CLI	Save approved running-config as baseline to bootflash
2	Guest Shell cron	Trigger Python auditor every 5 minutes
3	Python + vsh	Pull live running-config via /isan/bin/vsh
4	difflib	Compare live config against baseline, filter noise
5	Logger	Write timestamped results to /bootflash/config_audit_log.txt

2. Lab Environment

Parameter	Value
Hardware	Cisco Nexus N9K-C93180YC-EX
NX-OS Feature	Guest Shell (on-box Linux container)
Python Version	Python 3.6 (pre-installed in Guest Shell)
Shell Binary	/isan/bin/vsh (NX-OS CLI from Guest Shell)
Storage	/bootflash (persistent across reboots)
Scheduler	cron (inside Guest Shell)

Key insight: *The vsh binary was not in the default Guest Shell PATH. It was located at /isan/bin/vsh using the find command and hardcoded into the script — a real-world troubleshooting step that demonstrates understanding of NX-OS Guest Shell internals.*

3. Step-by-Step Implementation

Step 1 — Enable Guest Shell

Guest Shell is an on-box Linux container embedded in NX-OS. Enable it from the NX-OS CLI:

```
switch# guestshell enable
switch# guestshell
```

Step 2 — Save the Baseline Configuration

Before running the auditor, capture the current approved running-config as the baseline. This file becomes the reference point for all future comparisons:

```
switch# show running-config > bootflash:baseline_config.txt
```

Step 3 — Deploy the Python Auditor Script

The script is written directly onto bootflash from inside Guest Shell using the **cat heredoc** method (more reliable than vi for pasting large blocks):

```
cat > /bootflash/config_auditor.py << 'ENDOFFILE'
...
ENDOFFILE
```

Complete Script — config_auditor.py

```
#!/usr/bin/env python3

import subprocess
import difflib
import datetime
import os

BASELINE_PATH = "/bootflash/baseline_config.txt"
LOG_PATH      = "/bootflash/config_audit_log.txt"
LIVE_SNAP     = "/bootflash/live_config_snap.txt"

def get_live_config():
    result = subprocess.run(
        ["/isan/bin/vsh", "-c", "show running-config"],
        stdout=subprocess.PIPE,
        stderr=subprocess.PIPE
    )
```

```
    return result.stdout.decode("utf-8")

def filter_lines(lines):
    # Filter out dynamic lines that change every run (timestamps, etc.)
    skip = ["!Time:", "!Command:"]
    return [l for l in lines if not any(l.strip().startswith(s) for s in skip)]

def read_file(path):
    with open(path, "r") as f:
        return f.readlines()

def write_file(path, content):
    with open(path, "w") as f:
        f.write(content)

def log(message):
    timestamp = datetime.datetime.now().strftime("%Y-%m-%d %H:%M:%S")
    entry = "[{}] {}\n".format(timestamp, message)
    with open(LOG_PATH, "a") as f:
        f.write(entry)
    print(entry.strip())

def run_audit():
    if not os.path.exists(BASELINE_PATH):
        log("ERROR: Baseline config not found at " + BASELINE_PATH)
        return

    log("--- Audit started ---")

    live = get_live_config()
    write_file(LIVE_SNAP, live)

    baseline_lines = filter_lines(read_file(BASELINE_PATH))
    live_lines     = filter_lines(read_file(LIVE_SNAP))

    diff = list(difflib.unified_diff(
        baseline_lines,
        live_lines,
        fromfile="baseline",
        tofile="live",
        lineterm=""
    ))

    if not diff:
        log("PASS: No config drift detected.")
```

```
    else:
        log("DRIFT DETECTED: {} changed lines".format(len(diff)))
        for line in diff:
            line = line.strip()
            if line.startswith("+") or line.startswith("-"):
                log(line)

    log("--- Audit complete ---\n")

if __name__ == "__main__":
    run_audit()
```

Step 4 — Schedule with cron

Configure cron inside Guest Shell to run the auditor automatically every 5 minutes. This makes the solution fully autonomous — no manual intervention required:

```
# Open crontab editor
crontab -e

# Add this line:
*/5 * * * * python3 /bootflash/config_auditor.py

# Verify cron is active:
crontab -l
```

Step 5 — View Audit Results

Check audit logs at any time from either NX-OS CLI or Guest Shell:

```
# From NX-OS CLI:
switch# show file bootflash:config_audit_log.txt

# From Guest Shell:
tail -50 /bootflash/config_audit_log.txt

# Run a manual audit on demand:
guestshell run python3 /bootflash/config_auditor.py
```

4. Troubleshooting Encountered & Resolved

The following real issues were encountered and resolved during implementation:

Issue 1	capture_output TypeError
Problem:	Python 3.6 does not support the capture_output=True argument in subprocess.run().
Fix:	Replaced with explicit stdout=subprocess.PIPE, stderr=subprocess.PIPE. Also replaced f-strings with .format() for Python 3.6 compatibility.

Issue 2	FileNotFoundError: 'vsh'
Problem:	The vsh binary was not in the default Guest Shell PATH, causing the subprocess call to fail.
Fix:	Used find / -name 'vsh' 2>/dev/null to locate it at /isan/bin/vsh. Hardcoded the full path in the script.

Issue 3	False-positive drift on !Time: line
Problem:	NX-OS embeds a dynamic timestamp (!Time:) in show running-config output, causing every audit run to report drift even when nothing changed.
Fix:	Added a filter_lines() function that strips lines starting with !Time: and !Command: before comparison.

Issue 4	:wq saved inside the file
Problem:	When using vi, the :wq command was accidentally pasted as file content, causing a Python SyntaxError on execution.
Fix:	Switched to the cat heredoc method (cat > file << 'ENDOFFILE') which is more reliable for pasting large code blocks in terminal sessions.

5. Test Scenarios Executed

The following tests were performed to validate the auditor's drift detection capabilities. Each change was introduced deliberately, verified by the auditor, then reverted.

Test 1: Interface Description Change

Change applied:

```
configure terminal
interface Ethernet1/1
 description DRIFT_TEST
end
```

Revert command:

```
configure terminal
interface Ethernet1/1
 no description
end
```

Result: *DRIFT DETECTED — description line flagged*

Test 2: VLAN Addition

Change applied:

```
configure terminal
vlan 999
 name DRIFT_VLAN_TEST
end
```

Revert command:

```
configure terminal
no vlan 999
end
```

Result: *DRIFT DETECTED — vlan 999 and name lines flagged*

Test 3: ACL Creation

Change applied:

```
configure terminal
ip access-list DRIFT_ACL_TEST
 10 permit ip any any
end
```

Revert command:

```
configure terminal
```

```
no ip access-list DRIFT_ACL_TEST
end
```

Result: *DRIFT DETECTED — ACL and permit rule lines flagged*

6. Verification Screenshots

The following screenshots capture the actual execution on the Nexus 93180YC-EX device, demonstrating each phase of the project working in production.

Screenshot 1 — Test Commands Executed on Device

Shows all three drift test scenarios being configured directly on the switch: interface description change, VLAN 999 creation, and DRIFT_ACL_TEST access-list.

```
switch(config)# int eth1/1
switch(config-if)# decription DRIFT_TEST
                   ^
% Invalid command at '^' marker.
switch(config-if)# description DRIFT_TEST
switch(config-if)# end
switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
switch(config)# int eth1/1
switch(config-if)# no description
switch(config-if)# end
switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
switch(config)# vlan 999
switch(config-vlan)# name DRIFT_VLAN_TEST
switch(config-vlan)# end
switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
switch(config)# ip access-list DRIFT_ACL_TEST
switch(config-acl)# 10 permit ip any any
switch(config-acl)# end
switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
switch(config)# int eth1/10
switch(config-if)# spanning-tree bpduguard enable
                                  ^
% Invalid command at '^' marker.
switch(config-if)# shut
switch(config-if)# end
switch#
```

Screenshot 2 — Auditor Catching All Drift Events

Full audit log output showing the auditor detecting each configuration change in real time. Note the + and - diff lines clearly identifying what was added versus removed, with precise timestamps on every event.

[admin@guestshell ~]$ python3 /bootflash/config_auditor.py
[2026-04-02 20:57:22] --- Audit started ---
[2026-04-02 20:57:27] PASS: No config drift detected.
[2026-04-02 20:57:27] --- Audit complete ---
[admin@guestshell ~]$ crontab -e
```

7. Sample Audit Log Output

PASS — No Drift Detected

```
[2026-04-03 00:57:22] --- Audit started ---
[2026-04-03 00:57:27] PASS: No config drift detected.
[2026-04-03 00:57:27] --- Audit complete ---
```

DRIFT DETECTED — VLAN + ACL Change

```
[2026-04-03 00:19:04] --- Audit started ---
[2026-04-03 00:19:04] DRIFT DETECTED: 32 changed lines
[2026-04-03 00:19:04] --- baseline
[2026-04-03 00:19:04] +++ live
[2026-04-03 00:19:04] -vlan 1
[2026-04-03 00:19:04] +vlan 1,999
[2026-04-03 00:19:04] +vlan 999
[2026-04-03 00:19:04] +  name DRIFT_VLAN_TEST
[2026-04-03 00:19:04] --- Audit complete ---

[2026-04-03 00:19:49] --- Audit started ---
[2026-04-03 00:19:49] DRIFT DETECTED: 34 changed lines
[2026-04-03 00:19:49] +ip access-list DRIFT_ACL_TEST
[2026-04-03 00:19:49] +  10 permit ip any any
[2026-04-03 00:19:49] +vlan 1,999
[2026-04-03 00:19:49] +vlan 999
[2026-04-03 00:19:49] +  name DRIFT_VLAN_TEST
[2026-04-03 00:19:49] --- Audit complete ---
```

8. Real-World Value & TAC Relevance

How This Tool Helps Network Engineers

Use Case	How the Auditor Helps
Incident Root Cause Analysis	When a network outage occurs, TAC engineers check the audit log to instantly identify what changed and when — reducing MTTR from hours to minutes.
Change Management Compliance	Enterprises require all config changes to go through a change management process. The auditor provides an automatic audit trail of every deviation.
Security Policy Enforcement	Unauthorized ACL changes, new VLANs, or interface modifications are flagged immediately, enabling rapid security incident response.
Maintenance Window Verification	After a planned change window, run the auditor to confirm only the intended changes were made and nothing unintended was introduced.
24/7 Autonomous Monitoring	Runs every 5 minutes with zero human intervention. No external NMS, no SNMP polling, no external server — entirely self-contained on the device.

9. Resume Bullet Points

Use the following bullet points when adding this project to your resume for Network Engineer or Network Automation roles:

• Built on-box config drift detection tool using NX-OS Guest Shell (Python 3 + cron) on Cisco Nexus N9K-C93180YC-EX; automated config auditing against known-good baseline with timestamped deviation logging to bootflash.

• Developed autonomous network compliance monitoring using on-device Python scripting and vsh CLI integration; eliminated dependency on external management platforms by running entirely within NX-OS Guest Shell.

• Implemented scheduled config auditing on Nexus 93180YC-EX using Python difflib and cron; system detects unauthorized changes to interfaces, VLANs, and ACLs within 5 minutes of occurrence with zero manual intervention.

Skills Demonstrated

Skill	Evidence
NX-OS Guest Shell	Enabled, entered, and deployed scripts on-device
Python 3 (3.6 compatible)	Full script using subprocess, difflib, datetime, os
Linux / bash	cat heredoc, crontab, find, chmod, vsh path resolution
Network Automation	Autonomous on-box config compliance monitoring
Troubleshooting	Debugged 4 real errors: Python version, PATH, false positives, vi
Config Management	Baseline comparison, drift detection, audit logging
